## 1 Abstract

One of the fundamental problems in dependence modeling is the selection of an appropriate parametric copula model. In [1], it was shown that using the Akaike Information Criterion (AIC) based on the pseudo-log-likelihood is not justified for selecting parametric copula models. As a possible alternative, the authors proposed the information criterion  $xv_1$ , based on leave-one-out cross-validation, along with its approximation  $xv_{CIC}$ . In [2], the AIC and  $xv_{CIC}$  were compared, and only minor differences were observed. In the context of linear model selection, Jun Shao [3] demonstrated that the optimal selection procedure is leave- $n_v$ -out cross-validation, where  $n_v$  is of the same order as the sample size  $n$ , i.e.,  $n_v/n \xrightarrow{n \rightarrow \infty} 1$ . This idea is adapted to the context of copula model selection. Its performance is compared with that of AIC,  $xv_1$  and  $xv_{CIC}$ .

## 2 Used Information Criteria

In this simulation study, we compare four different copula selection methods:

- the Akaike Information Criterion (AIC),
- leave-one-out cross-validation  $xv_1$  and its approximation  $xv_{CIC}$ ,
- leave- $n_v$ -out cross-validation  $xv_{n_v}$ , where the validation set size  $n_v$  is of the same asymptotic order as the total sample size  $n$ .

We restrict our attention to the two-dimensional case and copula families with a one-dimensional dependence parameter  $\theta$ , such as Clayton, Gumbel, Joe, Frank, and Gaussian. Denote by  $\mathcal{X}_n = \{\mathbf{x}_i\}_{i=1}^n$  a random sample from the joint cdf

$$H(x_1, x_2) = C(F_1(x_1), F_2(x_2)),$$

where  $C$  is the copula, and  $F_1$  and  $F_2$  are continuous but unknown marginal cdfs. Also, define

$$\tilde{\mathbf{F}}_n(x_1, x_2) = \left( \tilde{F}_{n,1}(x_1), \tilde{F}_{n,2}(x_2) \right),$$

where  $\tilde{F}_{n,k}$  is the  $\frac{n}{n+1}$ -rescaled empirical cdf of the  $k$ th marginal, for  $k = 1, 2$ . The corresponding pseudo-observations are denoted by  ${}^p\mathcal{X}_n = \{{}^p\mathbf{x}_i\}_{i=1}^n$ , where  ${}^p\mathbf{x}_i = \tilde{\mathbf{F}}_n(\mathbf{x}_i)$ .

Note that [4, page 59] discusses why it is sufficient to simulate data from a copula model rather than a full bivariate model.

## 2.1 Akaike Information Criterion (AIC)

The AIC in the case of a one-dimensional parameter  $\theta$  is given by:

$$\text{AIC} = 2 \cdot {}^p\ell_n(\hat{\theta}_n) - 2,$$

where  ${}^p\ell_n$  is the pseudo-log-likelihood, which implicitly depends on the pseudo-observations  ${}^p\mathcal{X}_n$ , and is given by:

$${}^p\ell_n(\theta) = \sum_{i=1}^n \log[c_\theta({}^p\mathbf{x}_i)],$$

and  $\hat{\theta}_n = \operatorname{argmax}_{\theta \in \Theta} {}^p\ell_n(\theta)$  is the maximum pseudo-likelihood estimator.

## 2.2 Information Criterion Based on Leave-One-Out Cross-Validation

The selection procedure is based on the following quantity:

$$\text{xv}_1 = \frac{1}{n} \sum_{i=1}^n \log \left[ c_{\theta} \left( \tilde{\mathbf{F}}_{(-i)}(\mathbf{x}_i) \right) \right]_{\theta=\hat{\theta}_{(-i)}}, \text{ where} \quad (1)$$

- $\hat{\theta}_{(-i)} = \operatorname{argmax}_{\theta \in \Theta} \sum_{j \neq i} \log \left[ c_{\theta} \left( \tilde{\mathbf{F}}_{(-i)}(\mathbf{x}_j) \right) \right],$
- $\tilde{\mathbf{F}}_{(-i)}(x_1, x_2) = \left( \tilde{F}_{(-i),1}(x_1), \tilde{F}_{(-i),2}(x_2) \right)$ , where  $\tilde{F}_{(-i),k}$  is the  $\frac{n-1}{n}$ -rescaled empirical cdf of the  $k$ th marginal, computed from the sample  $\mathcal{X}_n$  excluding  $\mathbf{x}_i$ , for  $k = 1, 2$ .

Since computing (1) is computationally expensive, the authors of [1] recommend using  $\text{xv}_{\text{CIC}}$ , which is an asymptotically equivalent version and is given by:

$$\text{xv}_{\text{CIC}} = 2 \cdot \left( {}^p\ell_n(\hat{\theta}_n) - \hat{p}_n - \hat{q}_n - \hat{r}_n \right), \text{ where} \quad (2)$$

- $\hat{p}_n = \frac{1}{n \cdot \hat{J}} \sum_{i=1}^n [\phi_{\theta}({}^p\mathbf{x}_i)]_{\theta=\hat{\theta}_n}^2,$
- $\hat{q}_n = \frac{1}{n \cdot \hat{J}} \sum_{i=1}^n [\phi_{\theta}({}^p\mathbf{x}_i) \cdot \hat{z}_{\theta}({}^p\mathbf{x}_i)]_{\theta=\hat{\theta}_n},$
- $\hat{r}_n = \frac{1}{n} \sum_{i=1}^n \left[ \frac{\partial \log c_{\theta}({}^p\mathbf{x}_i)}{\partial u_1} \cdot (1 - {}^p x_{i,1}) + \frac{\partial \log c_{\theta}({}^p\mathbf{x}_i)}{\partial u_2} \cdot (1 - {}^p x_{i,2}) \right]_{\theta=\hat{\theta}_n},$
- $\phi_{\theta}(\mathbf{u}) = \frac{\partial \log c_{\theta}(\mathbf{u})}{\partial \theta},$
- $\hat{z}_{\theta}(\mathbf{x}) = \frac{1}{n} \sum_{k=1}^2 \sum_{i=1}^n \frac{\partial \phi_{\theta}({}^p\mathbf{x}_i)}{\partial u_k} \cdot (\mathbf{1}\{x_k \leq {}^p x_{i,k}\} - {}^p x_{i,k}),$
- $\hat{J} = -\frac{1}{n} \sum_{i=1}^n \left[ \frac{\partial^2 \log c_{\theta}({}^p\mathbf{x}_i)}{\partial \theta^2} \right]_{\theta=\hat{\theta}_n}.$

The generalization of formula (2) to higher dimensions can be found in [4, page 55].

### 2.3 Information Criterion Based on Leave- $n_v$ -Out Cross-Validation

Inspired by [3], we randomly draw, without replacement, a collection  $\mathcal{T}_n$  of  $b_n = O(n)$  subsets of  $\{1, \dots, n\}$ , each of size  $n_v$ , such that  $n_v/n \xrightarrow{n \rightarrow \infty} 1$ . Here, the  $n_v$  observations are used for validation, while the remaining  $n_c = n - n_v$  observations are used for parameter estimation. Denote by  $s_v \in \mathcal{T}_n$  the set of indices corresponding to the  $n_v$  validation observations. Then define the following quantity:

$$\text{xv}_{n_v} = \frac{1}{n_v b_n} \sum_{s_v \in \mathcal{T}_n} \sum_{i \in s_v} \log \left[ c_{\theta} \left( \tilde{\mathbf{F}}_{(-s_v)}(\mathbf{x}_i) \right) \right]_{\theta = \hat{\theta}_{(-s_v)}}, \text{ where}$$

- $\hat{\theta}_{(-s_v)} = \underset{\theta \in \Theta}{\operatorname{argmax}} \sum_{j \notin s_v} \log \left[ c_{\theta} \left( \tilde{\mathbf{F}}_{(-s_v)}(\mathbf{x}_j) \right) \right],$
- $\tilde{\mathbf{F}}_{(-s_v)}(x_1, x_2) = \left( \tilde{F}_{(-s_v),1}(x_1), \tilde{F}_{(-s_v),2}(x_2) \right)$ , where  $\tilde{F}_{(-s_v),k}$  is the  $\frac{n_c}{n_c+1}$ -rescaled empirical cdf of the  $k$ th marginal, computed from the sample  $\mathcal{X}_n$  excluding  $\{\mathbf{x}_i : i \in s_v\}$ , for  $k = 1, 2$ .

## 3 Setup of the Simulation Study

In this simulation study, the following settings were considered:

- The copulas  $C$  were chosen from one-dimensional parametric families (Clayton, Gumbel, Joe, Frank, Gaussian).
- Each copula was parameterized using different values of Kendall's tau. Specifically, for  $\tau \in \{0.25, 0.5, 0.75\}$ , we considered sample sizes  $n \in \{100, 250, 500\}$ . We also considered cases with weak dependence,  $\tau \in \{0.05, 0.1, 0.15, 0.2\}$ , and smaller sample sizes,  $n \in \{100, 200\}$ .
- For each pair of  $\tau$  and  $n$ , we conducted 5000 replications.
- For the calculation of  $\text{xv}_{n_v}$ , we used  $b_n = \lfloor 0.8n \rfloor$  and  $n_c = n^{0.9}$ .

## 4 Model Selection Counts

In the tables of this section, the first column, denoted as d.cop, indicates the true copula from which the data were simulated. Each row corresponds to one of the four selection methods, and the numbers in the cells represent how many times a specific copula (from the columns) was selected by that method across 5000 replications.

### 4.1 $\tau \in \{0.25, 0.5, 0.75\}$ and $n \in \{100, 200, 500\}$

Here, in most of the 5000 replications, the individual methods were able to select the correct copula. The only case of frequent incorrect model selection occurs in Table 1, where the data were simulated from the Gumbel copula, but  $xv_{CIC}$  more often selected the Joe copula.

Table 10: Copula selection using different information criteria ( $n = 500$ ,  $\tau = 0.75$ )

## 4.2 $\tau = 0.05$ and $n \in \{100, 200\}$

For extremely weak dependence,  $\tau = 0.05$  (when the copulas are close to the independence copula), and a small sample size of  $n = 100$ , Table 11 shows that in most of the 5000 replications, none of the proposed information criteria is able to correctly select the model when the true copula is Gumbel, Frank, or Gaussian. Note that our proposed  $xv_{n_v}$  fails to distinguish the Clayton copula in the majority of the 5000 replications, whereas the other information criteria are able to do so for the sample size  $n = 100$ .

One can see in Table 12 that increasing the sample size to  $n = 200$  doesn't help. It is interesting to observe that when the data are generated from the Gumbel copula,  $xv_{n_v}$  still fails to select the correct model in most replications, but it chooses the Gumbel copula more often than the other methods for both  $n \in \{100, 200\}$ .

Table 12: Copula selection using different information criteria ( $n = 200$ ,  $\tau = 0.05$ )

### 4.3 $\tau = 0.10$ and $n \in \{100, 200\}$

Here, we can see that for  $\tau = 0.10$  and the smaller sample size  $n = 100$ , the information criteria still fail to correctly select the Gumbel or Gaussian copula in most of the 5000 replications. However, when the sample size is increased to  $n = 200$ , all criteria most often select the true Gaussian copula.

Table 14: Copula selection using different information criteria ( $n = 200$ ,  $\tau = 0.10$ )

#### 4.4 $\tau \in \{0.15, 0.20\}$ and $n \in \{100, 200\}$

For  $\tau \in \{0.15, 0.20\}$ , all information criteria still struggle to correctly select the Gumbel copula when the sample size is  $n = 100$ . For  $n = 200$ , only  $xv_{CIC}$ , in the case of  $\tau = 0.15$ , fails to select the Gumbel copula in the majority of replications. Moreover, for  $\tau = 0.15$  and  $n = 100$ , information criteria AIC and  $xv_1$  fail to select the true Gaussian copula in the majority of replications.

Table 18: Copula selection using different information criteria ( $n = 200$ ,  $\tau = 0.20$ )

## 5 Coincidence percentages

The following tables show the coincidence percentages (i.e., the fraction of times two methods select the same model, regardless of whether it is the true model) between the cross-validation based information criteria and AIC across all considered copula families. The estimated 95 % confidence intervals are based upon the asymptotic approximation to the standard normal distribution, which can be used due to the size of the data-sets (5000 for each non-empty cell in the  $\tau$ -columns).

From the tables, one can see that  $xv_1$  is the method most similar to AIC in the sense of coincidence percentages. The approximation method  $xv_{CIC}$  is much closer to AIC under weak dependence, i.e.,  $\tau \in \{0.05, 0.10, 0.15\}$ , than the proposed method  $xv_{n_v}$ . However, for greater sample sizes,  $n \in \{250, 500\}$ , and for greater values of Kendall's tau,  $\tau \in \{0.25, 0.5, 0.75\}$ , the proposed method  $xv_{n_v}$  is closer to AIC than  $xv_{CIC}$ .

Note that in Table 19, for  $\tau \in \{0.5, 0.75\}$ , most of the confidence intervals are too narrow relative to the precision used in the tables. Therefore, they are reported as  $\pm 0.000$ .

|     | $\tau = 0.05$     | $\tau = 0.1$      | $\tau = 0.15$     | $\tau = 0.2$       | $\tau = 0.25$      | $\tau = 0.5$       | $\tau = 0.75$      | All                |
|-----|-------------------|-------------------|-------------------|--------------------|--------------------|--------------------|--------------------|--------------------|
| 100 | $99.77 \pm 0.060$ | $99.90 \pm 0.038$ | $99.92 \pm 0.036$ | $99.94 \pm 0.029$  | $99.97 \pm 0.021$  | $100.00 \pm 0.008$ | $99.98 \pm 0.016$  | $99.93 \pm 0.013$  |

Table 21: Coincidence of AIC and  $xv_{n_v}$ , with 95 % confidence intervals (all values multiplied by 100).

## 6 Hit rates

In the following two subsections, we present tables of hit rates. By the hit rate in each cell, we mean the fraction of times a specific criterion (from the rows) selected the correct copula (from the columns), divided by the number of replications (5000). The estimated 95 % confidence intervals are based upon the asymptotic approximation to the standard normal distribution, which can be used due to the size of the data sets (5000 for each cell).

Note that regardless of the sample size and the value of Kendall's tau, the most challenging copulas to identify for all criteria are Gaussian and Gumbel. Also, in the specific case when the true copula model is Gumbel, the proposed  $xv_{n_v}$  performed better (in terms of hit rates and their confidence intervals) than other criteria for all considered values of Kendall's tau and sample sizes.

### 6.1 $\tau \in \{0.05, 0.10, 0.15, 0.20\}$ and $n \in \{100, 200\}$

From the tables, one can see that in the case of weak dependence, i.e.,  $\tau \in \{0.05, 0.10, 0.15, 0.20\}$ , all information criteria perform poorly in correctly selecting the Gumbel, Frank, and Gaussian copulas.

| IC         | Clayton           | Gumbel            | Joe               | Frank             | Gaussian          |
